(54) Rotary blow molding machine and method

(57) A rotary blow molding machine 10 includes a horizontal main shaft 12 with a plurality of molds spaced around the shaft and mounted on the shaft by linear bearings for movement along the shaft. A shaft drive 22 rotates the shaft and molds around the axis of the shaft in steps 24, 26, and 28, and also along the shaft and molds between steps. Open molds are rotated from a lower container pick position 40 up to a mold open position 42, and then closed on a parison. The closed molds are shifted axially, rotating the main shaft and

the parison, up down. Further rotation of the shaft returns the molds to the mold pick position where the molds open and mold parison are ejected downwardly with gravity assist.

The machine further comprises two assembly drives 62 and 64, each comprising a shape device 26, accommodating both mold halves and a pair of drives 62, 64, 66, 68, 70, 72, and 74, and a pair of shape devices 26. A first end of drives 120, 168, and 74, and a second end of drives 134, 180, and 76, increases the clamp pressure.

FIG. 8

## Description

The invention relates to rotary blow molding machines and particularly to a rotary blow molding machine in which molds are indexed in steps around a horizontal axis and related methods.

Blow molded plastic containers are conventionally manufactured in high volumes using a continuously rotating horizontal rotary blow machine having a large number of molds mounted around the circumference of the machine. A continuously extruded parison is guided between open mold halves. With rotation, the molds close on the parison, the parison is blown, the molds open to eject containers and the cycle is repeated. The molds are continuously rotated at high speed to produce containers in high volumes. These machines are expensive to construct and operate. Change over to a different style container is expensive and time consuming due to the need to build and install a set of new molds. As many as 24 new molds may be required.

Blow molded plastic containers are conventionally manufactured in low volume using shuttle-type blow molding machines in which one or two molds are shifted back and forth between a parison extruder and a molding station. Each open mold is moved under the extruder and to either side of a downwardly growing parison. The mold is dwelled and closed on the parison, the parison is severed and then the mold is moved back to the molding station. The parison is blown at the molding station, the mold opens and the completed container is ejected. While shuttle-type blow molding machines may use multi-cavity molds to increase production, the production of these machines is limited and is considerably less than the production of continuously rotating horizontal rotary blow molding machines.

Intermediate production requirements for containers may be met by using a number of shuttle-type blow molding machines. This approach, however, is expensive in equipment cost and operation and maintenance cost.

U.S. Patent No. 4,919,607 discloses a prior step-type rotary blow molding machine for producing containers at intermediate production rates.

The invention is an improved horizontal step-type rotary blow molding machine having a production capacity greater than shuttle-type blow molding machines but less than continuously rotating multi-mold rotary blow molding machines. The machine includes four multi-cavity molds mounted 90° apart around a horizontal main shaft and shiftable axially along the shaft. The shaft and molds are indexed around the shaft in 90° steps and then dwelled for a period of time. During the dwell period the mold located in a retracted position at the bottom of the machine is shifted along the shaft to an ejection position, opened and molded articles are ejected downwardly from the machine, with gravity assist. After ejection, the next 90° indexing of the shaft rotates the open mold in the ejection position up to a parison capture position on the side of the machine where the mold is below a multi-parison extrusion head and surrounds downward growing parisons. During the next dwell period the mold closes, captures the parisons, the extruder bobs up to break the captured parisons away from the continuing growing parisons and the mold is shifted along the axis of the wheel back to a retracted position. Blow pins are then extended axially into the closed mold to calibrate the neck plastic accurately and the parisons are blown. During the next three 90° rotations of the shaft, the closed mold is retained in the retracted axial position with seated blow pins as the parisons cool to form blown containers and is rotated back to the bottom retracted position to complete one cycle of operation.

Each four cavity mold rotates 360° in 10 seconds so that the machine produces containers at the rate of 96 containers per minute. This rate is greater than the rate of production of two mold shuttle-type blow molding machines using the same size molds, but considerably less than the production of continuously rotating horizontal rotary blow molding machines.

The disclosed blow molding machine has the additional advantage that the molds capture downwardly growing parisons and then shift them away from the extrusion head and rotate them up and around the main shaft so that the blown containers are ejected at the bottom of the machine and are extracted from the molds in a downward direction, with gravity assist. Opening of the molds at the bottom of the machine for removal of the blown containers assures that any flash or possibly deformed containers fall down away from the molds and out of the machine.

The four station rotary blow molding machine is an efficient design with relatively low manufacture and maintenance cost, compared to shuttle-type blow molding machines. Continuously rotated horizontal blow molding machines are considerably more expensive.

Other objects and features of the invention will become apparent from the following description of an embodiment of the invention which refers to the accompanying figures in which

Figure 1 is a side view of the blow molding machine.  
Figure 2 is a top view of the machine, partially broken away.

Figure 3 is an end view of the machine taken generally along line 3--3 of Figure 2.

Figure 4 is a sectional view taken along line 4--4 of Figure 1 with parts removed.

Figure 5 is an end view of a mold assembly drive.

Figure 6 is an enlarged view of a portion of Figure 4.

Figure 7 is a side view taken generally along line 7--7 of Figure 3.

Figure 8 is a sectional view taken along line 8--8 of Figure 7.

Figures 9 and 10 are similar to Figures 7 and 8, but illustrating a different position.

Figure 11 is a sectional view taken generally along line 11-11 of Figure 3.

Figure 12 is a sectional view taken generally along line 12-12 of Figure 3.

Figure 13 is similar to Figure 12, but illustrating a different position.

Figure 14 is a partial side view of the machine.

Figure 15 is a view taken generally along line 15-15 of Figure 14.

Figure 16 is similar to Figure 14, but illustrating a different position.

Figure 17 is an enlarged view of portion A of Figure 2.

Figure 18 is a sectional view taken along line 18-18 of Figure 17, and

Figure 19 is similar to Figure 17, but illustrating a different position.

Horizontal rotary blow molding machine 10 includes an elongate, four-sided main shaft 12 journaled in bearings mounted on spaced apart supports 14 and 16 for rotation about its longitudinal axis. Three-sided support 18, shown in Figures 1 and 3, surrounds shaft 12 between supports 14 and 16. The shaft 12 is periodically rotated 90° in the direction of arrow 20 and then dwelled by shaft drive 22. A circular support plate 24 is mounted on main shaft 12 between supports 14 and 16 and lies in a plane perpendicular to the axis of the shaft. As illustrated in Figure 1, the top of support 18 is above plate 24.

Machine 10 includes four like mold assemblies 26 each mounted on one side of main shaft 12 by a linear bearing connection and moveable axially along the shaft between a retracted position 28 adjacent support 14 and an extended position 30 adjacent support 16. The mold assemblies are shifted back and forth along the main shaft between retracted and extended axial positions by a drive mechanism including a pair of mold assembly drives 32 and 34. The assembly drives are mounted on the side of support 14 away from plate 24 and extend through openings 36 and 38, respectively, in the support, as illustrated in Figure 3.

Drive 22 rotates the mold assemblies in 90° arcuate steps from extended bottom position 40 up to side position 42 where the parisons are captured, and after axial shift, down up to top locked position 44, down to locking side position 46, across from position 44, and down to the retracted bottom position 48. Positions 42-44 are illustrated in Figure 4. After rotation of the shaft through a 90° stop, drive 22 dwells so that the mold assemblies are located at the first respective positions for an interval of time prior to rotation or indexing to the next position. Rotation of the mold assemblies to intermediate positions 42 and 44 moves the assemblies into engagement with mold assembly drives 32 and 34 to permit axial shifting of the assemblies, and the main shaft and drive deliver the assemblies to positions 48 and 40, respectively, to permit move-

ment of the mold assemblies 26 along the main shaft.

Four cavity blow mold assemblies 50 are mounted on plate 24 adjacent the leading side of each support 48. A blow pin seating drive 52 is mounted on the top of frame 18 above and is engaged with the assembly 50 associated with the mold assembly in a retracted, side position 42.

Blow molding machine 10 includes a parison extruder 54 having a four parison extrusion head 56 located above the mold assembly, located in side retracted position 42 and in extended axial position 30. Head 56 extrudes four spaced parisons 58 downwardly toward and into the mold assembly. The extruder is supported on a subframe 60 which is pivotally mounted on base 62 at hinge connection 64. Hydraulic cylinder 66 is connected between the base and subframe such that rotation and extension of the cylinder powers and raises head 56 with respect to the mold assembly. The pivoting movement of the head facilitates positioning of the parisons in the mold assembly and breaking of the parisons from the portions structured in the closed mold.

Each mold assembly 26 includes a U-shaped mold carriage 68 having a base 70 and a pair of spaced arms 72 and 74 extending outwardly from the base. Linear bearing members 76 are mounted on the base 70 and engage an elongate bearing member 80 mounted on one side of the main shaft 12 to permit axial movement of the assembly along the shaft. Spaced apart bearing rollers 80 are secured to the end of the base adjacent support 16.

Each mold assembly 26 includes a four cavity blow mold having a first mold half 82 mounted on the inner surface of arm 72 and a second mold half 84 mounted on plate 86. Guide rods 88 on plate 86 extend through bearings on arm 74 to permit movement of mold half 84 toward and away from mold half 82. Each mold half includes four mold recesses which define mold cavities when the molds are closed. Assembly shift rod 92 extends outwardly from arm 74. Mold half shift rod 94 is journaled in a slide bearing in arm 74 and includes an inner end which is connected to plate 86 through a spring stack of Bellevue spring washers 96. A mold latch assembly 98 is mounted on the inner face of arm 74 and engages one end of undercut 100 in rod 94 to hold the mold halves closed.

The latch assembly is more fully illustrated in Figures 12 and 13. Assembly 98 includes an air cylinder 102 mounted on arm 74. The cylinder has piston rod which is connected to a slide latch plate 104. The plate is slidably mounted on the arm and moveable between an extended position shown in Figure 12 and a retracted position shown in Figure 13. Keyhole slot 106 is formed in plate 104. The aperture surrounds shift rod 94 and includes an inner end and a portion 108 adjacent cylinder 102 and a narrow slot portion 110 away from cylinder 102. Portion 108 is anti-rotational and outer diameter of rod 104 at portion 110 is less than a fully greater than the diameter of rod at undercut 100.

With cylinder 102 and plate 104 extended portion 108 surrounds rod 104 and permits free axial movement of the rod past the latch assembly. Retraction of cylinder 104 when the undercut 100 is located in aperture 105 shifts the plate to the position of Figure 13 where the undercut portion of the rod is fitted in narrow portion 110 and the rod is latched by engagement with the plate to prevent longitudinal movement.

Each mold is closed by mold assembly drive 32. Once closed, the latch assembly 98 shifts to latch the mold in the closed position and hold the mold closed during rotation of the mold from side circumferential position 42 through positions 44 and 46 to bottom circumferential position 40 where the assembly is unlatched and the mold is opened by mold assembly drive 34. Operation of the latch assembly and latching and unlatching of the molds are described in further detail below.

As shown in Figure 6, a pair of mold support rollers 112 are mounted on plate 24 at the trailing side of each output opening 48 across from the blow pin assembly 50 associated with the mold assembly in the opening. The mold assembly at circumferential position 42 rests on rollers 112 during extension of the blow pins into the closed mold. Rollers 112 hold the mold assembly against downward movement during extension of the blow pins.

Mold assembly drive 32 is located to one side of side circumferential position 42. Drive 32 includes a mounting plate 114 on support 14, a mold open and close drive 116 including a pair of carriages 118 slidably mounted on plate 114 for longitudinal movement back and forth along the plate and a mold shift drive 120. Drive 120 comprises a hydraulic cylinder mounted on the end of the plate furthest away from support 14 and having a piston rod joined to the carriage 118 adjacent the support. Extension and retraction of cylinder 120 moves the mold drive 116 back and forth to shift the attached mold assembly at circumferential position 42 between extended axial position 30 and retracted axial position 25.

As illustrated in Figure 8, drive 116 includes a body 122 mounted on carriages 118. A pair of parallel shift shafts 124 and 126 extend parallel to the axis of the main shaft through bearings at the forward end of body 122. Links 128 and 130 are mounted on the inner ends of shafts 124 and 126 and are pivotally connected to the ends of a pivotal toggle link 132 mounted on body 122. Link 130 extends rearwardly past the toggle link and is connected to the piston rod of hydraulic cylinder 134 also mounted on body 122. Extension of cylinder 134 extends shaft 126 outwardly from body 122 and retracts shaft 124 into body 122 and retraction of cylinder 134 from the extended position retracts 126 while extending shaft 124.

Rotation of each mold assembly 26 in the extended axial position 30 with an open empty mold up from the bottom circumferential position 42 to side circumferential position 42 rotates the ends of shift rods 92 and 94

into engagement with the ends of shift shafts 124 and 126 such that longitudinal movement of the shift shafts moves the shift rods. The two disengageable connections 95 between the shift shafts and shift rods are identical and are illustrated best in Figures 17-19. These figures illustrate the connection 95 between shaft 124 and rod 92, it being understood that a similar connection 95 is provided between shaft 126 and rod 94.

Rectangular C-shaped receiver 136 on the end of shaft 124 defines a central recess 138 extending between opposite sides of the receiver with an opening 140 in the recess facing away from shaft 124. Opening 140 is defined by a pair of opposed and outwardly facing bevel walls 142 on the receiver. Proximity sensor 144 is mounted in the receiver to one side of opening 140 and faces away from shaft 124.

Head assembly 146 is slidably mounted on reduced diameter portion 148 of rod 92. The reduced diameter portion of the rod extends between head 150 at the end of the rod and shoulder 152. Assembly 146 includes a frusto-conical head 154 slidably mounted on portion 148 and a circular proximity plate 156 extending perpendicularly to the axis of rod 92 and spaced a distance inwardly from head 154. A spring 158 is confined on portion 148 between shoulder 152 and plate 156 to bias assembly 146 against head 150 in a position shown in Figures 17 and 18.

The sides of frusto-conical head 154 are at the same angle as the bevel walls 142 of receiver 136 with the head having a maximum diameter away from head 150. When the assembly 146 is held against head 150 the axial distance between the outer end of the head 150 and the major base of the head equals the width of recess 138 to permit rotation of the rod into receiver 136 to form a slack-free connection between shaft 124 and rod 92. When the shaft and rod are locked together in this position, proximity plate 156 is located a short distance outwardly from sensor 144 so that the sensor generates a signal indicating proper engagement between the rod and shaft.

Figure 19 illustrates a condition when the rod and shaft are not engaged properly. Rod 92 has been rotated toward receiver 136 but, because of a misalignment between the rods and shaft, the head was not moved properly into the recess 138. In this case, the conical surface of head 154 engaged the bevel walls 142 of the receiver and assembly 146 was shifted away from head 150 compressing spring 158. Plate 156 is located an increased distance away from proximity sensor 144 which then generates a signal indicating that the shaft and rod are not properly engaged. Machine 10 is automatically shut down in response to the signal.

Mold assembly drive 34 shown in Figure 11 is mounted on support 14 to one side of bottom circumferential position 40. Drive 34 is similar to drive 32 and includes a mounting plate 160 mounted vertically on support 14 adjacent opening 38, a mold open and close drive 162 including spaced carriages 164 mounted on

•

—

•

100

5

•

mold drive which opens the molds at circumferential position 40 and closes the molds at circumferential position 42. Likewise, the two mold shift drives 120 and 166 operate as parts of a single drive which shifts the mold assemblies axially along the main shaft between the retracted and extended positions.

An arcuate assembly engagement plate or member 240 is mounted on the side of support 16 facing plate 24 and lies in a plane perpendicular to the axis of main shaft 12. Mold assemblies are in the axial retracted position 28 when rotated to bottom circumferential position 40. While in position 40 the assembly is axially shifted to the extended or container ejection position 30, opened and blow molded containers in the mold are ejected. The assembly with open molds in extended position 30 is then rotated up to circumferential position 42, with the open mold halves located to either side of growing parisons 58. During rotation of the extended mold assemblies from circumferential position 40 to position 42 alignment rollers 80 on the assemblies are rotated into engagement with plate 240 to assure that the mold assembly is in proper axial alignment. Proper alignment of the assembly assures that the mold halves are positioned to either side of the growing parisons and that the heads 154 on the ends of shift rods 92 and 94 are properly positioned for rotation into the receivers 136 on the ends of shift shafts 124 and 126 of mold assembly drive 32. Plate 240 is located between circumferential positions 40 and 42 to permit axial shifting of mold assemblies to the extended axial position when in the bottom circumferential position and to permit axial shifting of extended mold assemblies when in circumferential position 42 to the retracted axial position. The assemblies engage plate 242 during rotation between positions 40 and 42 or, if desired, a second alignment plate, like plate 240, may be provided to align mold assemblies in the retracted axial position during rotation down from side circumferential position 46 to bottom circumferential position 40, assuring a proper engagement between the mold assemblies and mold assembly drive 34.

Mold halves 82 and 84 are of conventional design and include interior cooling passages (not illustrated) which are connected to a water cooling system including inlet and outlet pipes (not illustrated) located on main shaft 12.

The horizontal rotary blow molding machine is operated by an automatic controller which is responsive to signals received from a number of sensors and switches on the machine. The controller is conventional and is not illustrated.

Operation of machine 10 will now be described by following one mold assembly 26 through a complete molding cycle, it being understood that the machine operates continuously and that all four mold assemblies 36 are continuously rotated through molding cycles. Parison extruder 54 extrudes four parisons 56 down from head 56 during operation of machine 10. When cyl-

inder 66's extended parison extruder head 56 is located a short distance above the mold halves in a mold assembly in the parison capture position. The parison thickness is controlled by the extruder head to facilitate breakaway of parisons captured in the mold halves when the head is bobbed up away from the closed mold.

At the beginning of a cycle of operation a mold assembly 26 is in the extended bottom ejection position with shift rods 92 and 94 engaging shift shafts 170 and 172 of mold assembly drive 34. The mold latch of the assembly is disengaged and cylinder 180 of drive 34 is retracted to hold the mold halves open. The cylinder of mold shift drive 166 is extended to locate the assembly in extended axial position 30. Containers blown during a prior cycle of operation have been ejected from the mold. Drive 22 is dwellled with one mold assembly in each of the four circumferential positions. This position is illustrated in Figure 1 of the drawings where the described mold assembly 26 is shown below main shaft 12 and adjacent support 16.

Next, drive 22 is actuated to rotate the main shaft 12, plate 24 and mold assemblies 20 in the direction of arrow 20. During rotation of the extended mold assembly from bottom circumferential position 40 to side circumferential position 42 the alignment rollers 80 on the assembly engage plate 240 to assure the assembly is in proper axial position as rotated into position 42. During rotation into position 42 the open empty mold halves 82 and 84 are rotated up to either side of the downwardly growing parisons 58. The heads 154 on shift rods 92 and 94 are rotated out of the receivers 136 on shift shafts 170 and 172 of mold assembly drive 34 and into receivers 136 on shift shafts 124 and 126 of mold assembly drive 32. Cylinder 134 of drive 32 is retracted and the cylinder of mold shift drive 120 is extended so that the receivers are in proper position and heads 154 are rotated into recesses 133 to engage the receivers as the mold assembly is rotated into circumferential position 42. The position of the mold assembly 26 and drive 32 is illustrated in Figures 7 and 8.

Next, cylinder 66 of parison extruder 54 is retracted to lower the extrusion head 56 and position the parisons in proper locations between the mold halves 82 and 84 with head 56 a short distance above the top of the mold halves. Cylinder 134 of drive 32 is then extended to simultaneously retract shift shaft 124 and extend shift shaft 126 and close the mold halves 82 and 84 on the parisons 58. During closing spring 96 is compressed and the shoulder on undercut 100 on shift rod 94 moves beyond the inner face of latch plate 104 permitting the pressurized cylinder 102 of latch assembly 98 to retract and shift the plate 104 from the unlatched position of Figure 12 to the latched position of Figure 13.

Upon closing of the mold and capture of the parisons, cylinder 66 in the parison extruder is extended to bob extrusion head 56 up and break the captured parison portions from the continuing growing new parisons. The extrusion head is bobbed up a sufficient distance

is assumed that the blow pin heads 56 and 57, with the mold assembly, during drive 34, are in the retracted position. The position of the mold assembly and drive 32 with the blow pins and the blow pin heads is illustrated in Figures 9 and 10.

Once the mold assembly has been ejected and the cylinder 180 has been raised, the hydraulic cylinder of mold drive 120 is retracted to shift the mold assembly at circumferential position 42 axially from extended axial position 30 to retracted axial or blow pin 38, underneath blow pin assembly 57. Head 56 is then lowered.

During rotation of the mold assembly to position 42, cylinder 226 of blow pin seating drive 52 is extended and cylinder 222 is retracted to shift the blow pins 210 and pins 212, as illustrated in Figure 14. After rotation, cylinder 226 is then retracted to shift receiver 222 over pins 212 and form a connection between the seating drive 52 and the adjacent blow pin assembly 57.

Upon shifting of the closed mold assembly to the retracted axial or blow pin 38 the necks of the mold cavities are axially aligned with the blow pins. Hydraulic cylinder 216 and air cylinders 202 are then extended to drive the blow pins axially down into the open air vents defined in necks of the cavities in the top of the mold. Axial lowering of the blow pins accurately defines or shapes the plastic at the neck to form the necks of the blow molded containers. After insertion of the blow pins, blow pins 104 are driven through the pins into the interiors of the extended receivers to push the pins against the walls of the mold cavities. After blowing, pressure is maintained on cylinder 206 to hold the blow pins in place. Pressure on cylinder 206 is released and cylinder 226 is then extended to shift receiver 222 out of and alignment with the blow pin assembly 57.

During blow molding the mold halves are held closed by cylinder 134 or open end closure 116 at a high clamping force of approximately 7 tons. After the blow and after the entry necking of the mold assembly, they move from position 40 to the pressure added to cylinder 114 and closed air back spring 166 to expand and seal the sections of receiver 110 against the closed end plate 104 so that the spring maintains a reduced clamping force of about 5 tons during cooling of the blow molded parts. After reduction of the clamping force, drive 22 indexes shaft 12 and the mold assembly is rotated to move heads 164 out of receivers 106.

After the mold assembly 28 has been rotated from circumferential position 40, cylinder 180 is extended and cylinder 184 is fully retracted to drive drive 32 into the position shown in Figure 9 ready to form the next open mold assembly. Drive 32 is rotated up to position 40.

Pressurized air, under full air pressure 216, is then applied to the mold assembly, which is rotated from circumferential position 40 to top circumferential position 44, as shown in Figure 4, and back to circumferential position 40. The mold assembly is then rotated to the position of Figure 10 and shaft 12 is rotated to position 30.

Driven by the fluid receiver.

During rotation of the mold assembly to position 40, the blow pin heads 56 are retracted and blow pin assembly 57, under 212, are retracted to withdraw blow pins 210 from the closed mold and free the assembly for rotation to the extended container ejection position.

After the mold assembly and the mold assembly has been rotated down to bottom circumferential position 40 and pins 92 and 94 have engaged the neck pins 106 of retracted drive 34, as illustrated in Figure 11, cylinder 22 drives rotation of the mold assembly and cylinder 166 is extended to shift the mold assembly from retracted position 28 to extended position 30.

Cylinder 180 is then extended to compress spring 166 to increase the clamping force and to drive pressure from the latch assembly 98. At this time, latch assembly cylinder 102 is pressurized so that upon extension of cylinder 180 and release of plate 104, cylinder 102 extends to shift the head plate 104 from the latched position of Figure 13 to the unlatched position of Figure 12.

Upon unlatching of the mold, cylinder 180 is retracted to open mold halves 82 and 84 so that the containers molded in the mold cavities are ejected from recesses 160 by eject pins, not illustrated. Bottle ejection equipment then removes the molded containers from machine 10. The containers are ejected downwardly from the bottom circumferential ejection position 40 with the benefit of gravity, thereby reducing the risk of molded containers in machine from machine or flash or blow defects in the molding. When in the container ejection position, the molds are below the main shaft so that flash and debris fall out from the machine. After the assembly has been rotated up from circumferential position 40 to circumferential position 42, cylinder 180 is retracted, cylinder 180 is extended and then released of pressure to cylinder 166 to shift the receivers 106 of drive 34 in position to receive the heads 164 of the next rotation of the mold assembly. Return of the assembly 28 to the extended axial position 18 and bottom circumferential position 40 and ejection of the containers completes a cycle for the assembly.

Main shaft drive rotates the mold 360° in approximately 1 second and is then delayed for approximately 1.5 seconds prior to the next rotation. Operation of the drive 34 in drive 32 completely rotates the mold 360° around the axis of the main shaft in 10 seconds with a rate production of 18 molded containers. The machine produces 18 containers per minute.

The event so far has been described using blow molds with mold halves and receivers, which insert and push into the cavity, the pins 104 push the plastic into the cavity and the pins 104 push the plastic into the cavity. After the mold assembly is rotated to the position 40, the containers are ejected from the bottom circumferential position 40 and the containers are ejected from the bottom circumferential position 40 and the containers are ejected from the bottom circumferential position 40 and the containers are ejected from the bottom circumferential position 40.

shaft. The invention has been described in connection with a rotary blow molding machine with four molds where the main shaft is rotated at 90° steps. The invention is not limited to a blow molding machine with four molds. The number of molds in the machine may be more than or less than four.

## Claims

1. A rotary blow molding machine (10) of the type including a main shaft (12) having a longitudinal axis, a plurality of blow molds (82-84) mounted on and spaced around the main shaft, a mold opening and closing drive (134-180) operable to open and close the molds, and a shaft drive (22) operable to rotate the main shaft and molds around the longitudinal axis, wherein the mold shift drive (120-166) is operable to shift molds along the main shaft between extended and retracted axial positions (30-28).
2. A rotary blow molding machine according to claim 1 wherein said axis is horizontal.
3. A rotary blow molding machine according to claim 1 or claim 2 including linear bearings mounting the blow molds (82-84) to the main shaft (12) and wherein said mold shift drive (120-166) shifts the molds along the main shaft (12).
4. A rotary blow molding machine according to any preceding claim including engageable and disengageable connections (95) between the molds (82-84) and the mold shift drive (120-166).
5. A rotary blow molding machine according to any preceding claim including engageable and disengageable connections (95) between the molds (82-84) and the mold opening and closing drive (134-180).
6. A rotary blow molding machine according to any preceding claim including a mold clamp (68-98) associated with each mold (82-84).
7. A rotary blow molding machine according to any preceding claim wherein said shaft drive (22) rotates the main shaft (12) and molds (82-84) around the axis in steps and dwells the shaft and molds in circumferential positions (40-42-44-46) between steps.
8. A rotary blow molding machine according to claim 7 wherein said positions (40-42-44-46) include an eject position (40) and a parison capture position (42) located above the eject position.
9. A rotary blow molding machine according to claim 8 including a parison extruder (54) at the parison capture position (42) and a blow assembly (52) adjacent the parison capture position.
10. A rotary blow molding machine according to claim 9 wherein said extruder (54) and said blow assembly (50-52) are spaced apart along the main shaft (12).
11. A rotary blow molding machine according to claim 9 or claim 10 wherein each blow assembly (50-52) includes a blow pin (206) and a pin drive (52).
12. A rotary blow molding machine according to claim 11 wherein each blow assembly (50-52) includes a blow pin seating drive (52).
13. A method of blow molding containers using a rotary blow molding machine (10) of the type having a main shaft (12), a plurality of molds (82-84) mounted on the shaft and spaced around the shaft, and a parison extruder (54), including the steps of:
  - a) locating an open mold (82-84) in a first axial position (30) on the main shaft and in a circumferential parison capture position (42) to surround a parison (58) extending from the extruder and then closing the mold on the parison;
  - b) shifting the closed mold and captured parison along the main shaft away from the first axial position to a second axial position (28) and blowing the parison in the mold;
  - c) rotating the closed mold and blown parison around the main shaft while cooling the blown parison to form a container; and
  - d) locating one closed mold and container at a circumferential container eject position (40), opening the closed mold and ejecting the container from the mold.

### (54) Rotary blow molding machine and method

(57) A rotary blow molding machine 10 includes a horizontal main shaft 12 with a plurality of molds spaced around the shaft and mounted on the shaft by roller bearings for movement along the shaft. A shaft drive 22 rotates the shaft and molds around the axis of the shaft in steps 40 to 46 and provides the shaft and molds between steps. Open molds are rotated from a lower container ejection position 40 up to a parison ejection position 42 and then to a parison ejection position 44. The parison ejection position 44 is a parison ejection position and

the parison is blown. Further rotation of the shaft returns the molds to the mold ejection position where the molds open and molded containers are ejected and ready with gravity assist.

The machine further comprises two assembly drives 62 and 64 each comprising a drive device 26 accommodating both individual drives and a pair of drives 32, 34, 36, 38, 40, 42, 44, 46, 48, 50, 52, 54, 56, 58, 60, 62, 64, 66, 68, 70, 72, 74, 76, 78, 80, 82, 84, 86, 88, 90, 92, 94, 96, 98, 100, 102, 104, 106, 108, 110, 112, 114, 116, 118, 120, 122, 124, 126, 128, 130, 132, 134, 136, 138, 140, 142, 144, 146, 148, 150, 152, 154, 156, 158, 160, 162, 164, 166, 168, 170, 172, 174, 176, 178, 180, 182, 184, 186, 188, 190, 192, 194, 196, 198, 200, 202, 204, 206, 208, 210, 212, 214, 216, 218, 220, 222, 224, 226, 228, 230, 232, 234, 236, 238, 240, 242, 244, 246, 248, 250, 252, 254, 256, 258, 260, 262, 264, 266, 268, 270, 272, 274, 276, 278, 280, 282, 284, 286, 288, 290, 292, 294, 296, 298, 300, 302, 304, 306, 308, 310, 312, 314, 316, 318, 320, 322, 324, 326, 328, 330, 332, 334, 336, 338, 340, 342, 344, 346, 348, 350, 352, 354, 356, 358, 360, 362, 364, 366, 368, 370, 372, 374, 376, 378, 380, 382, 384, 386, 388, 390, 392, 394, 396, 398, 400, 402, 404, 406, 408, 410, 412, 414, 416, 418, 420, 422, 424, 426, 428, 430, 432, 434, 436, 438, 440, 442, 444, 446, 448, 450, 452, 454, 456, 458, 460, 462, 464, 466, 468, 470, 472, 474, 476, 478, 480, 482, 484, 486, 488, 490, 492, 494, 496, 498, 500, 502, 504, 506, 508, 510, 512, 514, 516, 518, 520, 522, 524, 526, 528, 530, 532, 534, 536, 538, 540, 542, 544, 546, 548, 550, 552, 554, 556, 558, 560, 562, 564, 566, 568, 570, 572, 574, 576, 578, 580, 582, 584, 586, 588, 590, 592, 594, 596, 598, 600, 602, 604, 606, 608, 610, 612, 614, 616, 618, 620, 622, 624, 626, 628, 630, 632, 634, 636, 638, 640, 642, 644, 646, 648, 650, 652, 654, 656, 658, 660, 662, 664, 666, 668, 670, 672, 674, 676, 678, 680, 682, 684, 686, 688, 690, 692, 694, 696, 698, 700, 702, 704, 706, 708, 710, 712, 714, 716, 718, 720, 722, 724, 726, 728, 730, 732, 734, 736, 738, 740, 742, 744, 746, 748, 750, 752, 754, 756, 758, 760, 762, 764, 766, 768, 770, 772, 774, 776, 778, 780, 782, 784, 786, 788, 790, 792, 794, 796, 798, 800, 802, 804, 806, 808, 810, 812, 814, 816, 818, 820, 822, 824, 826, 828, 830, 832, 834, 836, 838, 840, 842, 844, 846, 848, 850, 852, 854, 856, 858, 860, 862, 864, 866, 868, 870, 872, 874, 876, 878, 880, 882, 884, 886, 888, 890, 892, 894, 896, 898, 900, 902, 904, 906, 908, 910, 912, 914, 916, 918, 920, 922, 924, 926, 928, 930, 932, 934, 936, 938, 940, 942, 944, 946, 948, 950, 952, 954, 956, 958, 960, 962, 964, 966, 968, 970, 972, 974, 976, 978, 980, 982, 984, 986, 988, 990, 992, 994, 996, 998, 1000.
